

A CLASS NUMBER RELATION IN FROBENIUS EXTENSIONS OF NUMBER FIELDS

COLIN D. WALTER

Let K/k be a normal extension of algebraic number fields whose Galois group G is a Frobenius group. Then K/k is said to be a Frobenius extension. Most of the structure of the unit group and of the ideal class group of K is determined by that of the subfields fixed by the Frobenius kernel N and by a complement F . Here this is investigated when G is a maximal or metacyclic Frobenius group. In particular, the results apply firstly to the normal closure of $k(\sqrt[p]{a})/k$ where $a \in k$ and p is a rational prime, and, secondly, when G is a dihedral group of order $2n$ for an odd integer n . A. Scholz, taking $n = p = 3$, was the first to consider this problem.

The first section describes some basic properties of the group ring $\mathbb{Z}[G]$ and the second section, which could be omitted in a preliminary reading, just serves to calculate a certain index in $\mathbb{Z}[G]$. The result is Theorem 2.1. In §3 the aim is to study the unit index Q which appears in the class number relation and a bound is obtained for it in Theorem 3.6. Then, in Theorem 4.4, the class number relation itself is derived. All the extraneous factors therein divide a power of the order n of N . This is explained in Theorem 5.3 by an underlying isomorphism between the maximal subgroups of the ideal class groups whose orders are prime to n .

The overall plan used to discover the class number relation is to eliminate the group of Minkowski units from R. Brauer's relation [1] and to calculate the consequent index in $\mathbb{Z}[G]$ by using regulators. When these ideas were first exhibited in an abstract of [11] at the Oberwolfach meeting in August 1975 discriminants were used instead of regulators, with the disadvantage that the index in $\mathbb{Z}[G]$ could be determined only for totally real fields. This restriction applies to W. Jehne's subsequent paper [6] on Frobenius extensions of \mathbb{Q} with maximal type. The general case for maximal Frobenius groups had already occurred in [9], but reappears here together with the metacyclic case. Some more specific metacyclic extensions have been examined by F. Halter-Koch and N. Moser in [2,3,4, and 8], while T. Honda in [5] has found the appropriate isomorphism of ideal class groups for general metacyclic Frobenius groups.

The author gratefully acknowledges the receipt of a grant from Trinity College, Cambridge.

§1. *Frobenius Groups.* Let G be a group with order $|G| = nf$ where n and f are co-prime and such that $g \in G$ implies $g^n = 1$ or $g^f = 1$. Suppose also that

$$N = \{g \in G \mid g^n = 1\}$$

is a proper normal subgroup of G . Then G is called a *Frobenius group* and N its *kernel*. Let $\tilde{S} \in \mathbb{Z}[G]$ denote the sum of the elements in a subset S of G . A *complement* of N is a subgroup F for which $\tilde{F}\tilde{N} = \tilde{G}$. There are precisely n such complements, which are conjugate under elements of N . They have order f and intersect pairwise in the identity, while N has order n . Hence

$$1.1 \quad \tilde{N} + \sum \tilde{F} = \tilde{G} + n \cdot \tilde{1},$$

where the sum extends over all complements F . This implies

$$1.2 \quad 1_N^G + f \cdot 1_F^G = 1_1^G + f \cdot 1_G^G,$$

where 1_H^G denotes the character on G induced by the unit character on a subgroup H .

The centraliser of an element of $N - 1$ is contained in N . Hence $N - 1$ decomposes into orbits of length f under conjugation by elements of F and f divides $n-1$. Thus G is called *maximal* if $f = n - 1$. In this situation N is an abelian group of prime exponent. Now suppose G is metacyclic. Then both N and F are cyclic with generators ν and ϕ respectively, say, which satisfy a relation $\nu^r \phi = \phi \nu$. Here n must be odd. From this point, it is assumed that G is of one of these two types.

1.3 DEFINITION. Let $\{v_i \in N \mid 0 \leq i \leq f-1\}$ be the set $N - 1$ when G is maximal and the set with $v_i = \nu^i$ when G is metacyclic. For the fixed complement F_0 , generated by ϕ when G is metacyclic, let Σ' and Π' denote sums and products over the f complements $\nu_i F_0 \nu_i^{-1}$.

Most other sums and products extend over the full set of n complements. Finally, for a left (respectively right) G -module X and a subgroup H of G let HX (respectively XH) be the subgroup of X fixed under the action of H . For example, NK and FK are the subfields of K fixed by N and F .

1.4 LEMMA. Let Z be the intersection of $\mathbb{Z}[N]$ with the centre of $\mathbb{Z}[G]$. Then

$$\mathbb{Z}[N] = \sum_i \nu_i Z$$

and this sum is direct up to elements in $\mathbb{Z}\tilde{N}$.

Proof. Z is generated by 1 and the elements $z_j = \sum_{h \in F} h^{-1} g_j h$ where the g_j are representatives of the $(n - 1)/f$ conjugacy classes in $N - 1$. The equality comes from $1 + \sum_i \nu_i = \tilde{N} \in \bigcap_i \nu_i Z$ in the maximal case. For the metacyclic case, the minimum polynomial $\prod_{h \in F} (x - h^{-1} \nu h)$ of ν over Z shows that ν^f , and therefore any power of ν , lies in $\sum_i \nu_i Z$. The directness is apparent from $\dim_{\mathbb{Z}} Z = 1 + (n-1)/f$.

1.5 THEOREM. For any $\mathbb{Z}[G]$ -module X define $X' = \sum FX$. Then X' is the $\mathbb{Z}[G]$ -module generated by any FX and $X' = \sum' FX$. Also define $X_0 = NX + X'$. Then the sum $X_0 = NX + \sum' FX$ is direct up to elements whose n th multiple lies in GX . Moreover, $nX \subset X_0$.

Proof. For $g \in N$ use 1.4 to choose $\alpha_i \in Z$ for which $g = \sum_i \nu_i \alpha_i$. If $x \in F_0 X$ then $gx = \sum_i \nu_i \alpha_i x \in \sum' FX$. Thus $\sum' FX$ is a $\mathbb{Z}[G]$ -module and contains every FX .

From 1.1 we have $nX \subset \tilde{N}X + \sum \tilde{F}X \subset X_0$. Also that equation yields

$$1.6 \quad \mathbb{Q}[G] = N\mathbb{Q}[G] + \sum' F\mathbb{Q}[G],$$

by the first part. A comparison of dimensions shows that this sum is direct up to elements in $\mathbb{Q}\tilde{G}$. Let $1 = e_N + \sum' e_F$ be a corresponding decomposition of 1 with $ne_N = \tilde{N}$ and $ne_F \in F\mathbb{Z}[G]$, say. Let $H, H' \in \{N, \nu_i F_0 \nu_i^{-1}\}$ be distinct. Then $ne_H \tilde{H}' \in \mathbb{Z}\tilde{G}$ by decomposing \tilde{H}' under 1.6. If $x_F \in FX$ for $F \neq H$ one finds that

$$ne_H x_F = ne_H (\tilde{N} - \sum_j \sum_{h \in F} h g_j h^{-1}) x_F = ne_H \tilde{N} x_F - \sum_j ne_H \tilde{F} g_j x_F \in GX.$$

Similarly, when $x_N \in NX$ one obtains $ne_{Fx_N} \in GX$ because $ne_F = \tilde{F}\alpha$ for some $\alpha \in \mathbb{Z}[N]$. Hence $ne_{Hx_H} \in GX$ if $x_{H'} \in H'X$. Consequently

$$nx_{H'} = \sum_H ne_H x_{H'} \equiv ne_{H'} x_{H'} \text{ modulo } GX.$$

Suppose $\sum_H x_H = 0$ with $x_H \in HX$. Then

$$0 = ne_{H'} \sum_H x_H \equiv ne_{H'} x_{H'} \equiv nx_{H'} \text{ modulo } GX$$

and $nx_{H'} \in GX$. Thus the sum for X_0 is direct as far as stated.

1.7 LEMMA. *Suppose G is metacyclic. Define $\beta_i \in \mathbb{Z}[G]$ by $(\nu-1)^i \beta_i = \tilde{F}_0(\nu-1)^i$. Then there is a direct sum decomposition of left $\mathbb{Z}[G]$ -modules*

$$\mathbb{Z}[G]/N\mathbb{Z}[G] = \bigoplus_{0 \leq i < f} \mathbb{Z}[N]\beta_i/N\mathbb{Z}[G].$$

Proof. Let β be the column vector $(\beta_0, \beta_1, \dots, \beta_{f-1})^T$ and ϕ the column vector $(1, \phi, \phi^2, \dots, \phi^{f-1})^T$. Then $M\phi = \beta$ for the matrix $M = (m_{ij})$ with $m_{ij} = (\nu^{r^j} - 1)^i / (\nu - 1)^i$. M is a Vandermonde matrix whose determinant is the unit $\prod_{i < j} (\nu^{r^j} - \nu^{r^i}) / (\nu - 1)$ of $\mathbb{Z}[N]/\mathbb{Z}\tilde{N}$. Hence M is invertible and 1 may be expressed as a linear combination of the β_i 's. The rest is now clear.

§2. *An Index Theorem.* Suppose C is a subgroup of order $c = 1$ or 2 generated by $\gamma \in G$. For any subgroup H and $g \in G$ write $HgC = \tilde{H}g\tilde{C}$ or $\frac{1}{2}\tilde{H}g\tilde{C}$ for the generators of $H\mathbb{Z}[G]C$ over \mathbb{Z} , and $|HgC| = |H||C|$ or $|H|$ respectively for their values under the unit character of G . Let $r_{2\gamma}(H)$ be the number of such generators with $2|H|$ elements, and set $r_\gamma(H) = \dim_{\mathbb{Z}}(H\mathbb{Z}[G]C/\mathbb{Z}\tilde{G})$.

2.1 THEOREM. *$\mathbb{Z}[G]C/(N\mathbb{Z}[G]C + \sum F\mathbb{Z}[G]C)$ has finite order $n^{fr_\gamma(N)/2}$ in the metacyclic case and $n^{(r_\gamma(N)+(f-1)r_\gamma(F)-1)/2}$ in the maximal case. The exponent of the group is precisely n .*

The rest of the section is devoted to a proof of this. There are three possibilities for γ :

$$\gamma = 1, \quad \gamma \in N-1, \quad \text{or} \quad \gamma \notin N.$$

Replacing γ by a conjugate does not change the order or the exponent of the quotient group. Thus if $\gamma \notin N$ it may be assumed that $\gamma \in F_0$. Because $F_0gC = \tilde{F}_0g\tilde{C}$ for $g \in N-1$ we have

$$\begin{aligned} 2.2 \quad r_{2\gamma}(F) &= 0, & n/2, & \text{and} & (n-1)/2; \\ r_\gamma(F) &= n-1, & (n-2)/2, & \text{and} & (n-1)/2; & \text{and} \\ r_\gamma(N) &= f-1, & f-1, & \text{and} & (f-2)/2, \end{aligned}$$

respectively in three cases.

From the proof of 1.5, $n\tilde{C}$ decomposes in $N\mathbb{Z}[G]C + \sum F\mathbb{Z}[G]C$ with component $\tilde{N}\tilde{C}$ in $N\mathbb{Z}[G]C$. So the exponent is n for metacyclic groups. For G maximal 1.1 yields the explicit decomposition $n\tilde{C} = \tilde{N}\tilde{C} + \sum_i \tilde{F}_0(1-\nu_i)\tilde{C}$ and hence an exponent n .

The Metacyclic Case. For $\gamma = 1$ the required index is

$$\begin{aligned} [\mathbb{Z}[G]/N\mathbb{Z}[G] : \sum' \mathbb{Z}[G]F/N\mathbb{Z}[G]] &= [\sum_i \mathbb{Z}[G]\beta_i/N\mathbb{Z}[G] : \sum_i \mathbb{Z}[G]F_0(v-1)^i/N\mathbb{Z}[G]] \\ &= \prod_i [\mathbb{Z}[M]\beta_i/N\mathbb{Z}[G] : (v-1)^i \mathbb{Z}[M]\beta_i/N\mathbb{Z}[G]] \\ &= \prod_i n^i = n^{f(f-1)/2} \end{aligned}$$

by 1.7. Otherwise the assumption $\gamma = \phi^{f/2}$ holds. Let $A_i = \tilde{C} \mathbb{Z}[G]\beta_i/N\mathbb{Z}[G]$. Then β_i may be replaced by

$$\beta_i' = \left(\frac{v}{v+1} \right)^i \beta_i$$

to give $(v^j + (-1)^i v^{-j})\beta_i'$ with $1 \leq j \leq (n-1)/2$ as a basis of A_i over \mathbb{Z} . $A_i \oplus vA_i$ is a $\mathbb{Z}[G]$ -module because if $\alpha \in A_i$ then $v^2\alpha = -\alpha + v(v + v^{-1})\alpha \in A_i \oplus vA_i$. When i is even,

$$\beta_i' = -\sum_j (v^j + v^{-j}) \beta_i' \in A_i \oplus vA_i \quad \text{so that} \quad A_i \oplus vA_i = \mathbb{Z}[G]\beta_i/N\mathbb{Z}[G].$$

When i is odd,

$$(v - v^{-1})\beta_i' \in A_i \oplus vA_i \quad \text{so that} \quad A_i \oplus vA_i = (v - 1)\mathbb{Z}[G]\beta_i/N\mathbb{Z}[G],$$

and this has index n in $\mathbb{Z}[G]\beta_i/N\mathbb{Z}[G]$. Hence if

$$B = \sum_i A_i = C\mathbb{Z}[G]/N\mathbb{Z}[G]$$

then $B \oplus vB$ has index $n^{f/2}$ in $\mathbb{Z}[G]/N\mathbb{Z}[G]$. $A_0 \oplus vA_0 = \mathbb{Z}[G]F_0/N\mathbb{Z}[G]$ shows that if $D = \sum C\mathbb{Z}[G]F/N\mathbb{Z}[G]$ then $D \oplus vD = \sum \mathbb{Z}[G]F/N\mathbb{Z}[G]$. Thus the required index $q = [B : D]$ is given by

$$\begin{aligned} n^{f(f-1)/2} &= [\mathbb{Z}[G]/N\mathbb{Z}[G] : \sum \mathbb{Z}[G]F/N\mathbb{Z}[G]] \\ &= n^{f/2} [B \oplus vB : D \oplus vD] \\ &= n^{f/2} q^2. \end{aligned}$$

The Maximal Case. When G is maximal the techniques of [11] are suitable for the order calculation. Define a pairing on $\mathbb{Z}[G] \times \mathbb{Z}[G]$ by $(x, y) = |G|^{-1} 1_1^G(xy^*)$ where $*$ is the involution induced by $g \mapsto g^{-1}$ for $g \in G$. If X is a subgroup of $\mathbb{Z}[G]$ with basis $\{x_i\}$ let

$$R(X) = |\det((x_i, x_j))|$$

be the regulator of X . This is independent of the choice of basis.

2.3 LEMMA. If $X = \sum F\mathbb{Z}[G]C$ then $R(X) = fn^{(f-1)(r_1(F)-1)} 2^{fr_2(F)}$.

Proof. Let $g, g' \in N-1$ be fixed. Then $ghg'h' = 1$ implies $h' = h^{-1}$ for $h, h' \in F$. But $ghg'h^{-1} = 1$ has only one solution $h \in F$. Hence $g\tilde{F}g'\tilde{F}$ contains the identity once. If $g \in N-1$ and $g' = 1$, or $g' \in N-1$ and $g = 1$, then 1 does not appear in $g\tilde{F}g'\tilde{F}$, but it occurs f times for $g = g' = 1$.

Choose $S \subseteq N - 1$ so that $\{FsC \mid s \in S \text{ or } s = 1\}$ is a basis of $F\mathbb{Z}[G]C$. If $t, t' \in N - 1$ and $s, s' \in S$ then $(t'Fs'C, tFsC)$ is c times the multiplicity of l in $t^{-1}t'\tilde{F}s'\tilde{C}s^{-1}\tilde{F}$. Since $s'\gamma s^{-1} \notin F$ for $c = 2$ the value of the pairing is given by:

	$t = t'$	$t \neq t'$
$s = s'$	cf	$c^2 - c$
$s \neq s'$	0	c^2

Also $(\tilde{G}, \tilde{G}) = nf$ and $(\tilde{G}, t\tilde{F}s\tilde{C}) = cf$. Take $\{\tilde{G}, tFsC \mid t \in N-1, s \in S\}$ for a basis of X . The corresponding matrix for $R(X)$ includes $|S| \times |S|$ blocks, one for each pair $t, t' \in N - 1$. Observe that $|S| = r_\gamma(F)$ and let J, J_r , and J_c be the $r_\gamma(F) \times r_\gamma(F)$, $1 \times r_\gamma(F)$, and $r_\gamma(F) \times 1$ matrices consisting entirely of unit entries. Then the regulator may be calculated as follows :

$$\begin{aligned}
 R(X) &= \begin{vmatrix} nf & cfJ_r & cfJ_r & \dots & cfJ_r \\ cfJ_c & cfI & c^2J - cI & \dots & c^2J - cI \\ cfJ_c & c^2J - cI & cfI & \dots & c^2J - cI \\ \vdots & \vdots & \vdots & \ddots & \vdots \\ cfJ_c & c^2J - cI & c^2J - cI & \dots & cfI \end{vmatrix} \\
 &= \begin{vmatrix} nf & 0 & 0 & \dots & cfJ_r \\ cfJ_c & cnI - c^2J & 0 & \dots & c^2J - cI \\ cfJ_c & 0 & cnI - c^2J & \dots & c^2J - cI \\ \vdots & \vdots & \vdots & \ddots & \vdots \\ cfJ_c & c^2J - cnI & c^2J - cnI & \dots & cfI \end{vmatrix} \\
 &= |cnI - c^2J|^{n-2} \begin{vmatrix} nf & cfJ_r \\ cf^2J_c & cI + c^2(n-2)J \end{vmatrix} \\
 &= \{(cn)^{r_\gamma(F)-1} (cn - c^2r_\gamma(F))\}^{f-1} f \begin{vmatrix} n & cJ_r \\ cJ_c & cI \end{vmatrix} \\
 &= fn^{(f-1)(r_\gamma(F)-1)} (n - cr_\gamma(F))^f c^{fr_\gamma(F)} \\
 &= fn^{(f-1)(r_\gamma(F)-1)} 2^{fr_{2\gamma(F)}}, \quad \text{by 2.2.}
 \end{aligned}$$

Let $\rho : \mathbb{Z}[G]C \rightarrow L_\gamma = \mathbb{Z}[G]C/\mathbb{Z}\tilde{G}$ be the natural map and define a pairing on $L_\gamma \times L_\gamma$ by $(\rho x, \rho y) = |G|^{-1}(1_1^G - 1)(xy^*)$ for $x, y \in \mathbb{Z}[G]C$ and the involution $*$: $g \in G \mapsto g^{-1}$. Suppose X is a subgroup of L_γ . Take $\{x_j\}$ in $\mathbb{Z}[G]C$ such that $\{\rho x_j\}$ is a basis of X . Then $\{\tilde{G}, x_j\}$ is a basis of $\rho^{-1}X$. So

$$R(\rho^{-1}X) = \left\| \begin{matrix} (x_i, x_j) & (x_i, \tilde{G}) \\ (\tilde{G}, x_j) & (\tilde{G}, \tilde{G}) \end{matrix} \right\|_{i,j}.$$

But $(\rho x, \rho y) = (x, y) - |G|^{-1}(x, \tilde{G})(\tilde{G}, y)$ for $x, y \in \mathbb{Z}[G]C$. Hence row operations give $R(\rho^{-1}X) = |G|R(X)$ for the obvious definition of $R(X)$. Now 2.3 yields

2.4 LEMMA. $R(\sum FL_\gamma) = n^{(f-1)r_\gamma(F)-f} 2^{fr_{2\gamma}(F)}$.

If $x, y \in \mathbb{Z}[G]C$ satisfy $\rho x \in NL_\gamma$ and $\rho y \in \sum FL_\gamma$ then $(\rho x, \rho y) = 0$. Also the sum $NL_\gamma + \sum' FL_\gamma$ is direct by 1.5. Thus,

2.5 LEMMA. $R(NL_\gamma + \sum FL_\gamma) = R(NL_\gamma) R(\sum FL_\gamma)$.

From [11], 3.5 and 3.3, the following facts may be recalled :

2.6 $R(HL_\gamma) = |G|^{-1} |H|^{r_\gamma(H)+1} 2^{r_{2\gamma}(H)}$ for a subgroup H ;

2.7 $R(Y) = [X : Y]^2 R(X)$ for subgroups X, Y of L_γ for which $[X : Y]$ is defined.

Combining equations 2.4–2.7 for $X = L_\gamma$ and $Y = NL_\gamma + \sum FL_\gamma$ gives the order of

$$\mathbb{Z}[G]C / (N\mathbb{Z}[G]C + \sum F\mathbb{Z}[G]C)$$

as

$$[X : Y] = \{R(NL_\gamma) R(\sum FL_\gamma) / R(L_\gamma)\}^{\frac{1}{2}} = \{n^{r_\gamma(N)+(f-1)(r_\gamma(F)-1)}\}^{\frac{1}{2}}.$$

The power of 2 is eliminated by observing that $r_{2\gamma}(H) = 1_H^G (1 - \gamma)/2$ and evaluating 1.2 at $(1 - \gamma)/2$.

§3. *The Unit Group.* Suppose the normal extension K/k of number fields has the Frobenius group G as its Galois group. Let U and W be the groups of units and roots of unity in K .

3.1 LEMMA. $W = NW$ and $FW = GW$.

Proof. Let $H = \text{Gal}(K/k(W))$. Then H is normal in G and G/H is abelian. The former property implies $H \subset N$ or $N \subseteq H$. However, if $H \subset N$ then G/H is Frobenius and therefore not abelian. Thus $N \subseteq H$ and $W = NW$. Now set $H' = \text{Gal}(K/k(FW))$. Then, similarly, $N \subseteq H'$. But $F \subseteq H'$ also. Therefore $H' = G$ and $FW = GW$.

The unit group U will be written additively when the notation makes this more convenient. In particular, for a subgroup H of G let $\mathbb{Q}HU$ be the subgroup of units with some non-trivial multiple (*i.e.* power) fixed by H . Define

3.2 $I(H) = [HU \cap \mathbb{Q}GU : GU + HW]$.

It was shown in [11, §4] that $I(H)$ divides $[G : H]$.

3.3 LEMMA. $\mathbb{Q}GU = N\mathbb{Q}GU + F\mathbb{Q}GU$ and the sum is direct up to elements in GU . Hence $I(1) = I(N)I(F)$.

Proof. The three groups modulo $GU + W$ have orders $I(1)$, $I(N)$, and $I(F)$ which divide nf , f , and n respectively. The sum is therefore direct because $(n, f) = 1$. Choose $a, b \in \mathbb{Z}$ such that $an + bf \equiv 1 \pmod{nf}$. Take $\epsilon \in \mathbb{Q}GU$ and write $[\epsilon]$ for its class modulo $GU + W$. Since G acts trivially on $\mathbb{Q}GU/(GU + W)$ it follows that $[\epsilon] = [(an + bf)\epsilon] = [\tilde{N} a\epsilon] + [\tilde{F} b\epsilon] \in (N\mathbb{Q}GU + F\mathbb{Q}GU)/(GU + W)$.

Application of 1.5 shows that $Q = [U : U_0]$ is finite and divides a power of n . Theorem 4.1 of [11] proves that $[\mathbb{Q}FU : FU + W]$ divides f , which is prime to n , and $FU + W \subset U_0$. Therefore

3.4 $\mathbb{Q}FU \subset U_0$.

Now the directness of 1.5 for U together with 3.3 yield

3.5 LEMMA. $\mathbb{Q}FU = FU + N\mathbb{Q}GU$.

3.6 THEOREM. Let $r(H)$ be the rank of HU/HW . Then $Q = [U : U_0]$ divides $In^{(f-1)(r(F)-r(G))}$ for $I = [\mathbb{Q}NU : \mathbb{Q}NU \cap U_0]$ and I in turn divides n .

Proof. For any $\mathbb{Z}[G]$ -module X the quotient $X/\mathbb{Q}HX$ is torsion-free. Take $x \in X$ with image in $H(X/\mathbb{Q}HX)$. Then $(|H| - \tilde{H})x \in \mathbb{Q}HX$ and so $x \in \mathbb{Q}HX$. Thus $\mathbb{Q}H(X/\mathbb{Q}HX) = 0$. In particular, $V = U/\mathbb{Q}NU$ has $\mathbb{Q}GV \subset \mathbb{Q}NV = 0$. Hence $V_0 = \sum' FV$ and 1.5 shows this sum is direct. If $\varepsilon \in U$ has image in $\mathbb{Q}FV$ then $\tilde{F}\varepsilon - f\varepsilon \in \mathbb{Q}NU$. So $[FV : (FU + \mathbb{Q}NU)/\mathbb{Q}NU]$ divides a power of f and the same is true of $[V_0 : (U_0 + \mathbb{Q}NU)/\mathbb{Q}NU]$. However, the latter index divides Q and thus a power of n . Therefore $V_0 = (U_0 + \mathbb{Q}NU)/\mathbb{Q}NU$ and $Q = [U : U_0] = [V : V_0]I$. From 1.5 the exponent of V/V_0 divides n . Also $\mathbb{Q}FV = FV$ and the rank of V_0/FV is $(f-1)(r(F) - r(G))$. Thus the index $[V : V_0] = [V/FV : V_0/FV]$ divides $n^{(f-1)(r(F)-r(G))}$. Finally I divides n by Theorem 4.1 of [11].

3.7 LEMMA. The norms $N_{K/FK} U = \tilde{F}U$ satisfy $FU = \tilde{F}U + GU$.

Proof. Let S be a set of representatives for the conjugacy classes of $N - 1$ under F . If $\varepsilon \in FU$ then

$$\varepsilon = \left(\tilde{N} - \sum_{h \in F} \sum_{g \in S} hgh^{-1} \right) \varepsilon = \tilde{N}\varepsilon - \tilde{F}\tilde{S}\varepsilon \in GU + \tilde{F}U.$$

§4. *The Class Number Relation.* Let $\{C_i\}$ be the set of decomposition groups in G for one prime divisor in K of each of the $r = r(G) + 1$ infinite primes in k . They are defined up to conjugacy which depends on the chosen embedding of K into \mathbf{C} . Suppose L and L_i satisfy the exact sequences of $\mathbb{Z}[G]$ -modules

$$0 \rightarrow \mathbb{Z} \rightarrow \bigoplus_{i=1}^r \mathbb{Z}[G]C_i \rightarrow L \rightarrow 0,$$

where $n \in \mathbb{Z} \mapsto n \oplus_i \tilde{G}$; and

$$0 \rightarrow \mathbb{Z} \rightarrow \mathbb{Z}[G]C_i \rightarrow L_i \rightarrow 0,$$

where $n \in \mathbb{Z} \mapsto n\tilde{G}$. In both cases let G act trivially on \mathbb{Z} . Both sequences are exact when fixed under the action of a subgroup H . Let $L_0 = NL + \sum FL$; $L_{i0} = NL_i + \sum FL_i$; $Q^* = [L : L_0]$; and $Q_i^* = [L_i : L_{i0}]$. Then Q^* and Q_i^* are finite by Theorem 1.5. Moreover,

$$\begin{aligned} L/L_0 &\cong \{\oplus_i \mathbb{Z}[G]C_i\} / \{\oplus_i (N\mathbb{Z}[G]C_i + \sum F\mathbb{Z}[G]C_i)\} \\ &\cong \oplus_i \{(\mathbb{Z}[G]C_i) / (N\mathbb{Z}[G]C_i + \sum F\mathbb{Z}[G]C_i)\} \cong \oplus_i L_i/L_{i0}. \end{aligned}$$

Consequently,

$$4.1 \quad Q^* = \prod_{i=1}^r Q_i^*.$$

The index Q_i^* is just the order of the group in Theorem 2.1 with $C = C_i$. If $r_i(H) = \dim HL_i$ then $\sum_i (r_i(H)+1) = \dim HL + 1 = r(H) + 1$ is the number of infinite primes in HK . Thus $r(H)$ is the rank of the unit group HU/HW . Combining 2.1 with 4.1 yields:

4.2 LEMMA. $Q^* = n^{f(r(N) - r(G))/2}$ in the metacyclic case and
 $Q^* = n^{(r(N) - r(G) + (f-1)(r(F) - 2r(G) - 1))/2}$ in the maximal case.

Let a bar denote the canonical map $U \rightarrow U/W$ and choose a submodule M of \bar{U} which is $\mathbb{Z}[G]$ -isomorphic to L . Recall the definitions of $I(H)$ and Q in 3.2 and 3.6.

4.3 LEMMA.

$$\frac{[\bar{U} : M][\overline{GU} : GM]^f}{[\overline{NU} : NM][\overline{FU} : FM]^f} = \frac{Q}{Q^* I(F)^{f-1}}.$$

Proof. Begin by observing that $(\mathbb{Q}GU \cap HU)/W = \overline{GHU}$ so that $I(H) = [\overline{GHU} : \overline{GU}]$. Also $G\bar{U} = \mathbb{Q}GU/W = (\mathbb{Q}GU \cap U_0)/W = \overline{GU_0}$ by 3.3. For convenience, let $V = G\bar{U}$. Then

$$\begin{aligned} Q^* [\bar{U} : M] / [\overline{GU} : GM] I(1) Q &= [\overline{U_0} : M_0][GM : V] = [\overline{U_0} / V : (M_0 + V)/V] \\ &= [(\overline{NU} + V)/V : (NM + V)/V] \prod' [(\overline{FU} + V)/V : (FM + V)/V] \\ &= [\overline{NU} : NM + G\overline{NU}] [\overline{FU} : FM + G\overline{FU}]^f \\ &= [\overline{NU} : NM][\overline{FU} : FM]^f / [G\overline{NU} : NM \cap G\overline{NU}] [G\overline{FU} : FM \cap G\overline{FU}]^f \\ &= [\overline{NU} : NM][\overline{FU} : FM]^f / I(N)I(F)^f [\overline{GU} : GM]^{f+1}. \end{aligned}$$

Now apply 3.3.

4.4 THEOREM. Suppose the normal extension K/k of number fields has a maximal or metacyclic Frobenius group G as its Galois group. Let $h(H)$ be the class number and $r(H)$ the rank of the unit group HU of the subfield fixed by a subgroup H of G . If the kernel N and a complement F have orders n and f respectively then

$$\frac{h(1)h(G)^f}{h(N)h(F)^f} = QI(F)^{1-f} n^{-A},$$

where

- $Q = [U : NU \prod' FU]$ with \prod over the complements F ;
- $I(F)$, defined in 3.2, is the order of $(FU / GU)_{\text{tor}}$ and divides n ;
- $A = \frac{1}{2}\{r(N) - r(G) + (f-1)(r(F) - 2r(G) + 1)\}$ in the maximal case; and
- $A = (f - 1) + \frac{1}{2}f(r(N) - r(G))$ in the metacyclic case.

The quotient group U/U_0 defining Q has exponent dividing n and it has order bounded by 3.6. The product $U_0 = NU \prod' FU$ defined in 1.3 is direct up to units whose n th powers lie in k .

Proof. The form of Brauer’s class number relation [1] which is required here is given in [10, Theorem 4.1]. This shows that

$$\frac{h(1)h(G)^f}{h(N)h(F)^f} = \frac{nf |W| [\overline{U} : M] |GW|^f [\overline{GU} : GM]^f}{f |NW| [\overline{NU} : NM] n^f [\overline{FU} : FM]^f} = \frac{n^{1-f} Q}{Q^* I(F)^{f-1}}$$

by 3.1 and 4.3. Now 4.2 yields the stated relation.

§5. *The Class Groups.* Let $C(H)$ be the part of the ideal class group of HK formed from the classes whose orders are prime to n .

5.1 THEOREM. *For any Frobenius group the following sequence is exact under the maps induced by extension of ideals.*

$$0 \rightarrow C(G) \rightarrow C(F) \rightarrow FC(1)/GC(1) \rightarrow 0.$$

Proof. The sequence is exact at $C(G)$ because $C(G)$ has order prime to the degree n of FK/GK . The two central maps compose to give the zero map. Suppose \mathcal{E} is a class of $C(F)$ which maps into $GC(1)$. It is necessary to show that if \mathfrak{a} is an ideal such that $\mathfrak{a}^n \in \mathcal{E}$ then the class of the norm $N_{FK/GK} \mathfrak{a}$ in $C(G)$ maps to \mathcal{E} . This will establish the exactness at $C(F)$. Let us consider all ideals to be extended to K and write the group of such ideals additively. Then $(g-1)\mathfrak{a}$ is principal for $g \in G$ because the image of \mathcal{E} in $C(1)$ is fixed by G . Suppose $(g-1)\mathfrak{a} = (\alpha_g)$. If $h \in F$ then

$$(\alpha_g) = (g-1)\mathfrak{a} = (g-1)h\mathfrak{a} = h(h^{-1}gh-1)\mathfrak{a} = h(\alpha_{h^{-1}gh}).$$

Thus it may be assumed that $h\alpha_{h^{-1}gh} = \alpha_g$ and $\alpha_1 = 1$. Let S be a set of representatives for the conjugacy classes of $N-1$ under F . Then

$$(\tilde{N}-n)\mathfrak{a} = \sum_{g \in N} (\alpha_g) = \left(\sum_{g \in S} \sum_{h \in F} h^{-1}\alpha_g \right) = \left(\sum_{g \in S} \tilde{F}\alpha_g \right)$$

which is the extension of a principal ideal of FK . Finally, to prove the surjectivity, let \mathcal{E}' be a class of $FC(1)/GC(1)$ and \mathfrak{a} an ideal whose image is in \mathcal{E}' . With S as above,

$$\mathfrak{a} = \left(\tilde{N} - \sum_{h \in F} \sum_{g \in S} hgh^{-1} \right) \mathfrak{a} \sim (\tilde{N} - \tilde{F}\tilde{S}) \mathfrak{a}$$

where \sim is equality up to a principal ideal. Thus the ideal $-\tilde{F}\tilde{S} \mathfrak{a}$ in $C(F)$ has image in \mathcal{E}' because $\tilde{N} \mathfrak{a}$ is in a class of $GC(1)$. Hence the map is surjective and this completes the proof. Theorem 1.5 yields :

5.2 LEMMA. *Let X be a $\mathbb{Z}[G]$ -module such that the order of X/GX is finite and prime to n . Then there is a direct sum decomposition*

$$X/GX = NX/GX + \sum' FX/GX.$$

5.3 THEOREM. *The maximal subgroups $C(H)$ of the ideal class groups of the HK with orders prime to n satisfy*

$$C(1)/C(N) \cong \bigoplus_{i=1}^f C(F)^{(i)}/C(G),$$

where $C(F)^{(i)} \cong C(F)$ and the embeddings $C(N) \hookrightarrow C(I)$ and $C(G) \hookrightarrow C(F)^{(i)}$ are induced by extension of ideals.

Proof. Replace $C(N)$ by $NC(1)$ and $C(F)^{(i)}/C(G)$ by $FC(1)/GC(1)$ using 5.1. Now apply 5.2.
